The HEART Pathway Randomized Trial: Identifying Emergency Department Patients With Acute Chest Pain for Early Discharge

Simon A. Mahler, Robert F. Riley, Brian C. Hiestand, Gregory B. Russell, James W. Hoekstra, Cedric W. Lefebvre, Bret A. Nicks, David M. Cline, Kim L. Askew, Stephanie B. Elliott, David M. Herrington, Gregory L. Burke and Chadwick D. Miller

Background

The HEART Pathway is a decision aid designed to identify emergency department patients with acute chest pain for early discharge. No randomized trials have compared the HEART Pathway with usual care.

Methods and Results

Adult emergency department patients with symptoms related to acute coronary syndrome without ST-elevation on ECG (n=282) were randomized to the HEART Pathway or usual care. In the HEART Pathway arm, emergency department providers used the HEART score, a validated decision aid, and troponin measures at 0 and 3 hours to identify patients for early discharge. Usual care was based on American College of Cardiology/American Heart Association guidelines. The primary outcome, objective cardiac testing (stress testing or angiography), and secondary outcomes, index length of stay, early discharge, and major adverse cardiac events (death, myocardial infarction, or coronary revascularization), were assessed at 30 days by phone interview and record review. Participants had a mean age of 53 years, 16% had previous myocardial infarction, and 6% (95% confidence interval, 3.6%–9.5%) had major adverse cardiac events within 30 days of randomization. Compared with usual care, use of the HEART Pathway decreased objective cardiac testing at 30 days by 12.1% (68.8% versus 56.7%; *P*=0.048) and length of stay by 12 hours (9.9 versus 21.9 hours; *P*=0.013) and increased early discharges by 21.3% (39.7% versus 18.4%;*P*<0.001). No patients identified for early discharge had major adverse cardiac events within 30 days.

Conclusions

The HEART Pathway reduces objective cardiac testing during 30 days, shortens length of stay, and increases early discharges. These important efficiency gains occurred without any patients identified for early discharge suffering MACE at 30 days.

Genomics: biological ageing and cardiovascular disease

Telomeres are the extreme ends of eukaryotic chromosomes and are involved in cell cycle control and maintenance of chromosomal stability.

In West of Scotland Primary Prevention Study (WOSCOPS)

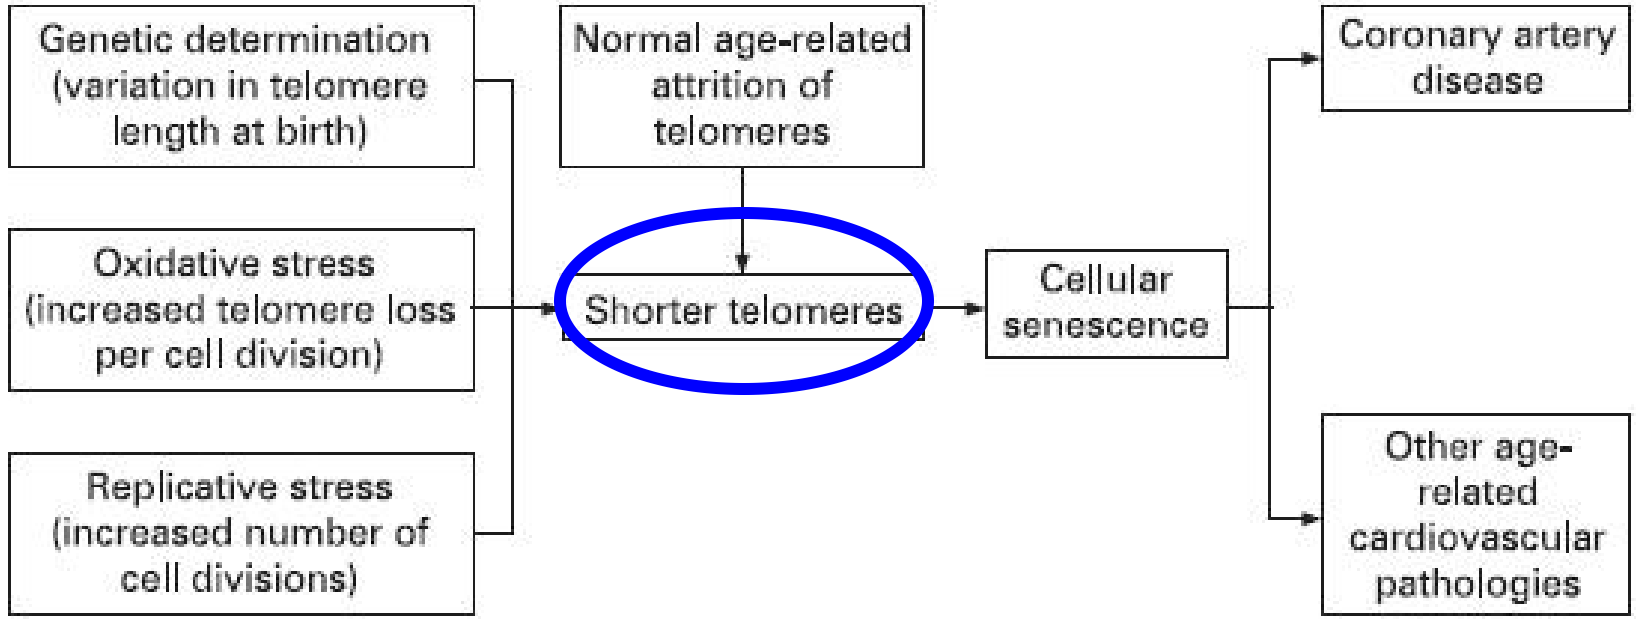
odds ratio for MACE was x 2 in placebo pts

in the lower two tertiles of telomere length

versus the highest.

Samani NJ, from heart.bmj.com 2008

Genomics: biological ageing and cardiovascular disease



Factors affecting telomere length and how these could explain interindividual variation in risk of age-related cardiovascular diseases. The telomere hypothesis postulates that shorter telomeres contribute to a risk of coronary artery disease and other cardiovascular diseases through its impact on cellular senescence. In turn, telomere length is affected by age and a number of other factors whose impact vary between individual subjects.

Samani NJ, Heart 2008

Genomics: …genetic variant predisposing to CAD on chromosome 1 associates with serum cholesterol

… the novel 7 CAD-associated loci in the vicinity of the PSRC1 and CELSR2 genes on chromosome 1 (1p13.3), showed a strong association with total cholesterol.

The CAD-associated risk allele A of rs599839 (allele frequency 0.78) was associated with a 0.17-mmol/l (95% CI 0.10 to 0.24 mmol/l) higher serum cholesterol level per allele copy ($P = 3.84 \times 10{-}6$).
An association of rs599839 with LDL cholesterol was also shown in 1,090 cases with myocardial infarction ($P = 0.0026$).

Nilesh J, J Mol Med 2008.

Genomics

The presence of 2 alleles is strogly associated with risk of MI or CAD

shows the same risk for CAD
as the presence of
multiple RF for atherosclerosis

Right now, most medical treatments are designed for the average patient.

But one size doesn't fit all, and treatments that are very successful for some patients don't work for others. **Think about it:**

- If you need glasses, you aren't assigned a generic pair. You get a prescription customized for you.
- If you have an allergy, you get tested to determine exactly what you're allergic to.
- If you need a blood transfusion, it has to match your precise blood type.

…fin'ora:

Chest Pain in Acute Myocardial Infarction
Are Men From Mars and Women From Venus?

Louise Pilote, MD, MPH, PhD

In 1995, John Gray published a book entitled *Men Are From Mars, Women Are From Venus*.[1] The premise of this book was that men and women have fundamental psychological differences that make them experience the world and respond to situations in widely distinct ways. Could the same be true when it comes to chest pain in acute myocardial infarction (AMI)? Dissention remains in the medical literature, in the minds of the clinicians, and in the public at large as to whether men and women have fundamentally different presentations of AMI.

Related article page 241

Several studies have shown that the most common symptom at presentation in men and women is chest pain.[2] Reports vary in the proportion of patients who present without chest pain, but the prevalence of presentation without chest pain is higher in women. More information on chest pain–associated symptoms and symptoms accompanying presentation without chest pain might prove useful in improving the diagnosis of AMI in women.

With the above premises in mind, Rubini Gimenez et al asked whether detection of sex-specific chest pain characteristics (CPCs) would allow emergency department physicians to diagnose AMI in women more accurately.[3] The authors conducted a large prospective cohort study in 7 European centers (5 Swiss, 1 Italian, and 1 Spanish) to investigate the predictive value of CPCs. From 2006 to 2012, the investigators assembled a cohort of 2475 patients, 796 women and 1679 men, who presented to an emergency department within 12 hours of the onset of acute chest pain. The median age of men was more than 10 years younger that of women (59 vs 70 years), and a higher proportion of men had had a previous AMI (28.2% vs 15.1%) and revascularization (32.9% vs 17.3%). Thirty-four predefined CPCs were collected with regard to the location and size of the area of pain, pain quality, radiation, onset, duration, dynamics, severity, and the aggravating and relieving factors (eg, response to nitrates). Chest pain characteristics were collected in the emergency department through interviews by trained physicians who were blinded to the electrocardiography and cardiac troponin test results. All patients underwent electrocardiography and chest radiography; levels of cardiac troponin at presentation and serially thereafter were measured if clinically indicated. All medical records were reviewed twice for adjudication of the final diagnosis by 2 independent reviewers.

Alternative diagnoses in patients discharged after CPU management with no evidence of CAD (n = 870).

Conti A, Am Heart J, 2002

Chest Pain - Imipramine

- 50 mg nightly for 3 wks
- 52% reduction in chest pain episodes
- Suggested visceral analgesic effect
  - *Cannon R, et al. N Engl J Med 1994; 330:1411-7*

- 15 healthy male volunteers
- Balloon inflation volume at pain threshold higher on imipramine
  - *Peghini PL, et al. Gut 1998; 42:807-13*

Differential cont
Gastrointestinal

- Non-esophageal
  - Biliary
  - Peptic ulcer disease
  - pancreatitis
- **Esophageal**
  - Reflux diseases
  - Esophageal spasm
  - Esophageal hypersensitivity
  - Pill esophagitis
  - HIV-AIDS diseases
  - Lye ingestion
  - Achalasia

Impression

- Non-cardiac chest pain most likely of esophageal origin.
- Pathophysiology
  - Pathological acid reflux
  - Non-acid reflux
  - Disturbed Motility
  - Visceral hypersensitivity/Brain-gut interactions
    - Chemoreceptor, mechanoreceptor, thermoreceptor malfunction
    - Altered cerebral processing of sensory data
  - Psychological abnormalities- somatoform disorder

Next Step

What should be done next?

- Endoscopy
- Ambulatory pH monitoring
- Combined Impedance-pH testing
- Esophageal manometry
- Acid suppression therapy.

Endoscopy

- Insensitive- EE only in 5-10% of cases[1].
- Highly specific
- Costly
- Invasive
- Not likely to change management
- Can help identify structural abnormalities associated w GERD, stricture, Schatzki's ring, hiatal hernia

- 1. Cherian et al, Dis Esophagus 1995; 8:129

Ambulatory pH monitoring

- Using endoscopy, a probe is attached to the distal esophagus to measure changes in pH for 48 hours.
- Can be done on or off PPIs.
- Diary allows correlation between symptoms and acid reflux.
- Sensitive and specific
- Can help rule out PPI resistance
- Costly
- Invasive- greater pt discomfort (occ chest pain)
- Can miss up to 25% of cases of reflux-not due to “acid”

Esophageal Manometry

- A thin probe is inserted intranasally and advanced into distal esophagus.
- Measurements are recorded as the pt is asked to swallow sips of water.
- Goal is to rule out motility disorders of the esophagus as cause for chest pain.
- Not very sensitive but specific
- Tensilon (Edrophonium) provocation can be used to increase sensitivity but it decreases the specificity by increasing the number of false positives.
- Poorly tolerated by most patients/invasive/costly.

Acid suppression therapy

- Also called the “PPI Test”
- Empiric trial of double dose PPI therapy for 1 to 8 weeks.
- Readily available
- Cheap
- Noninvasive
- Well tolerated with few if any side effects.
- Both diagnostic and therapeutic advantages

Management

- If the PPI test fails, then one should proceed with endoscopy/pH monitoring +/- impedance testing depending on availability.
- Should it be performed on PPI therapy or not? It depends…..
  - Is it GERD?
  - Is it PPI resistance? (up to 20%).[1]

1. Leite et al. Am J Gastroenterol 1996; 91:1572

Summary

- NCCP is a very common problem with high cost to the healthcare system and significant morbidity to the patient.
- The most common cause of NCCP is GERD.
- An empiric trial of high dose PPI therapy is the single most effective approach to dealing with NCCP.

Differential Diagnosis

- Cardiovascular
- CP related to Hyperadrenergic states
- Chest wall
- Pulmonary
- Mediastinal
- Psychiatric

- GI
  - Esophageal
    - Reflux
    - Rupture
    - Spasm
    - Esophagitis
  - Pancreatobiliary
    - Pancreatitis
    - Cholecystitis
    - Cholangitis
    - Biliary Colic
  - PUD

Non-Cardiac Chest Pain

- More than 50% of patients presenting to ED
  - Sustained concern 1yr after negative LHC
    - 51% unable to work, 47% limited activity, 44% still with perceived CAD
- Esophageal spasms?
  - 910 patients with negative LHC
    - 28% with abnormal motility (10% due to spasms)
- GERD most common cause
  - Abnormal acid exposure in 50% in recurrent noncardiac chest pain

Non-Cardiac Chest Pain

- Esophageal Hypersensitivity
  - Lower threshold for non-cardiac chest pain with intraesophageal balloon distension
    - 24 patients with CP and negative cardiac workup, EGD, Motility studies, 24h pH probe
    - Typical CP reproduced in 83% compared to none in controls
    - Related to altered cerebral processing rather than abnormal receptors

Approach to patient

- Exclude CAD
  - Angiography eliminates life-threatening disease as cause of CP
- Clues for esophageal etiology
  - Pain persistent for > 1 hr
  - Postprandial pain
  - Lack of pain radiation
  - Associated esophageal symptoms (heartburn, regurgitation, dysphagia)
  - Pain relieved by antacid ingestion
- Relief with NTG does not indicate cardiac origin
  - Out of 459 patients, 39% relieved (35% with, 41% w/o)

GERD

- Definition: Symptoms or complications resulting from the reflux of gastric contents into the esophagus or beyond, into the oral cavity (including larynx) or lung.
- Further classified as the presence of symptoms without erosions on endoscopic examination (non-erosive disease or NERD) or GERD symptoms with erosions present (ERD)

Guidelines for the Diagnosis and Management of GERD, Katz, et al; *Am J Gastroenterol* 2013;108:308-328

Symptoms and Epidemiology

- Prevalence of 10-20% of Western world
- Clinically troublesome heartburn is seen in about 6% of the population
- Regurgitation was reported in 16%
- Distinguishing cardiac from non-cardiac chest pain is required before considering GERD as a cause of chest pain.
- Although the symptom of dysphagia can be associated with uncomplicated GERD, its presence warrants investigation for a potential complication including an underlying motility disorder, stricture, ring, or malignancy

Symptoms and Epidemiology

- Extraesophageal symptoms: chronic cough, asthma, chronic laryngitis, other airway symptoms
- Atypical symptoms including dyspepsia (38%), epigastric pain, nausea, bloating, and belching may be indicative of GERD but overlap with other conditions.
- QOL: increase time off work, decrease physical functioning, nocturnal > daytime symptoms, sleep disturbances

Symptoms and Epidemiology

- Symptom frequency does not change with age
- Symptom intensity decreases after age 50
- Aging increases prevalence of erosive esophagitis (LA Grades C and D)
- Barrett's Esophagus increases in prevalence after age 50 (Caucasian males); M > F
- Men: more Erosive Esophagitis; Women: more NERD
- Esophageal Adenocarcinoma 8:1 male to female
- GERD associated with increased BMI, waist circumference, wt gain, ERD, and Barrett's Esophagus

Diagnosis

- Made by combination of:
  - Symptom presentation
  - Objective testing with endoscopy
  - Ambulatory reflux monitoring
- Heartburn and regurgitation correlates poorly with presence of Erosive Esophagitis
  - Sensitivity 30-76% ; Specificity 62-96%
- Empiric PPI trial
  - Sensitivity 78%; Specificity 54%

Diagnosis

- Non-cardiac chest pain
  - Generally associated with GERD
  - Generally responds to aggressive acid suppression
  - Cost-effective (when cardiac cause excluded)
    - Response greater than placebo in patients with objective evidence of GERD (ERD on EGD and/or abnormal pH monitoring)
- Dysphagia
  - Alarming symptom requiring endoscopy

IMPROVING PATIENT CARE

Triage of Patients with Acute Chest Pain and Possible Cardiac Ischemia: The Elusive Search for Diagnostic Perfection

Lee Goldman, MD, and Ajay J. Kirtane, MD*

Few diagnostic decisions in medicine have been more heavily researched than the approach to the patient with acute chest pain. Despite the advances in both diagnosing and treating patients presenting with this symptom, cases of missed myocardial infarctions still cause substantial morbidity and mortality. This article examines a case in which a patient was sent home from the emergency department after presenting with chest pain and was subsequently found to have a myocardial infarction. In the context of the case, the article discusses clinical decision making about the diagnosis and triage of patients presenting with acute chest pain or with symptoms consistent with possible cardiac ischemia. A standardized approach to addressing the management of these patients is essential, given the adverse consequences of missing a life-threatening condition.

State-of-the-Art Evaluation of ED patients with potential ACS

Clinical Feature	Likelihood Ratio (95% CI)
Increased likelihood of AMI	
Described as pressure	1.3 (1.2–1.5)
Pain in chest or left arm	2.7*
Chest pain radiation	
To right arm or shoulder	4.7 (1.9–12)
To left arm	2.3 (1.7–3.1)
To both left and right arm	7.1 (3.6–14.2)
To both arms or shoulders	4.1 (2.5–6.5)
Chest pain most important symptom	2.0*
Chest pain associated with exertion	2.4 (1.5–3.8)
Worse than previous angina or similar to prior AMI	1.8 (1.6–2.0)
History of MI	1.5–3.0†
Nausea or vomiting	1.9 (1.7–2.3)
Diaphoresis	2.0 (1.9–2.2)
Third heart sound	3.2 (1.6–6.5)
Hypotension (systolic BP <80 mm Hg)	3.1 (1.8–5.2)
Pulmonary crackles	2.1 (1.4–3.1)
Decreased likelihood of AMI	
Pleuritic chest pain	0.2 (0.1–0.3)
Described as sharp	0.3 (0.2–0.5)
Positional chest pain	0.3 (0.2–0.5)
Reproduced by palpation	0.3 (0.2–0.4)
Inframammary location	0.8 (0.7–0.9)
Not associated with exertion	0.8 (0.6–0.9)

Challenges Facing Cardiology, Nuclear Medicine and Emergency Medicine Today

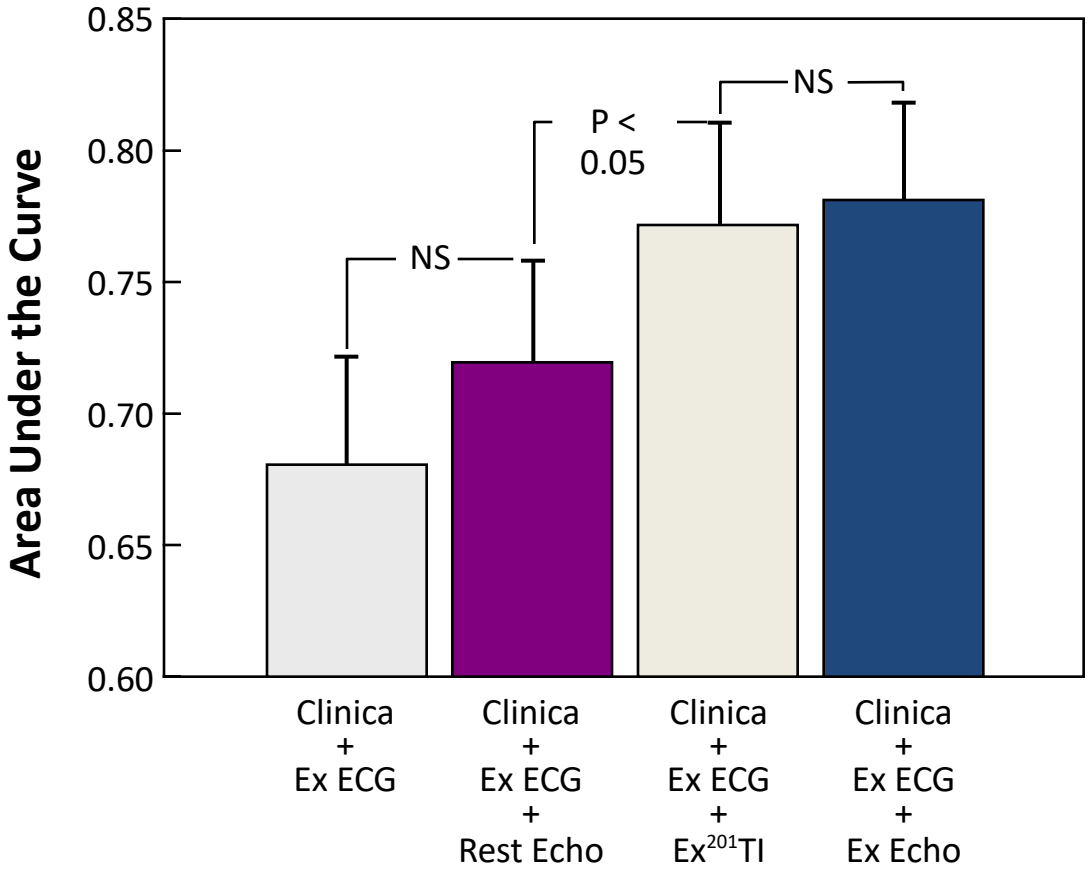
- Increasing imbalance between infinite demand and finite resources
- Fundamental changes in diagnostics

Today's Dilemma:

- Choosing rational vs. rationed care

“Diagnostic value of testing in CP patients”

- Clin (clinical parameters)
- Ex-ECG (Stress)
- Echo (resting)
- Echo (Stress)
- SPECT (stress)



Choosing rational

Finding the Holy Grail Is Not a Short-Term Project

the HEART Pathway, which showed 100% sensitivity using 2 sets of conventional troponins

CL Atzema, MJ Schull. Circulation 2016

External validation:

the HEART Pathway had a miss rate of 1.7% (95% confidence interval, 1.0–2.9)

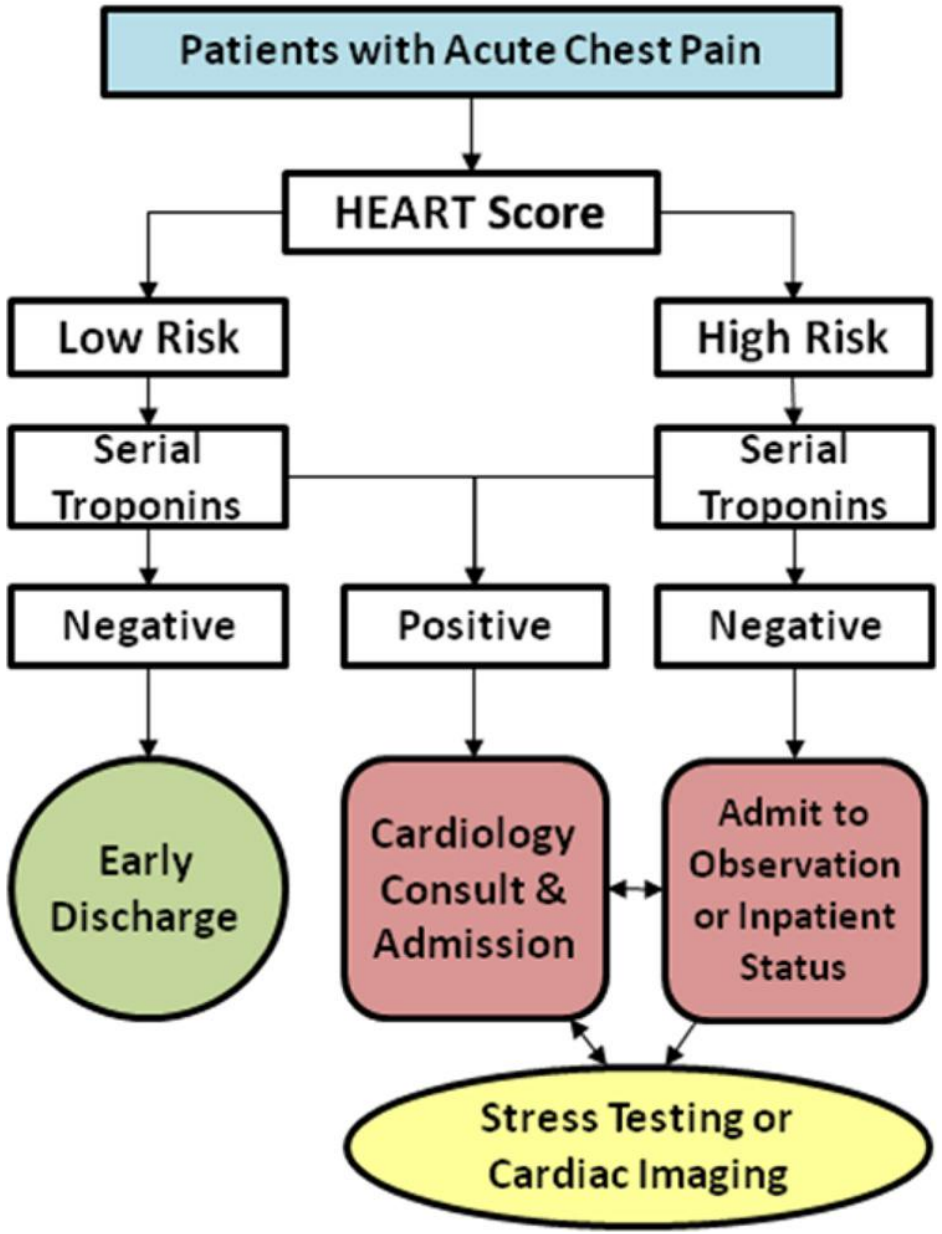
HEART Pathway



USL NordOvest Toscana protocollo Chest Pain screening
…se “rischio intermedio”

1
se dolore toracico tipico, ECG non diagnostico, cTnI normale non diagnostica,
paziente < 65 anni:
AngioTC-Coronarica

2
se dolore toracico tipico, ECG non diagnostico, cTnI normale non diagnostica,
paziente ≥ 65 anni:
SPECT Miocardica (Scintigrafia miocardica da stress)

Nel sesso femminile è consigliata comunque angio-TC-coronarica
Successiva eventuale ulteriore definizione diagnostica con SPECT Miocardica

In atto protocollo per appuntamento informatico con
radiodiagnostica e medicina nucleare:
il paziente del PS alla dimissione riceve data e ora dell’esame prospettato

53 pazienti positivi allo screenong con angioTCcoronarica o SPECT o entrambi
Che sono stati riconosciuti con cardiopatia ischemica critica e non critica

…via ringrazio per l’attenzione

Regione Toscana
