## 8.4 Anaemia

Anaemia is common in patients with NSTEMI-ACS.<sup>451</sup> Persistent or worsening anaemia in patients with NSTEMI-ACS is associated with increased mortality, recurrent MI, and major bleeding.<sup>452</sup> However, it is uncertain whether anaemia itself is the determinant for poorer outcome or rather a marker of comorbidity.

Given that the treatment of NSTEMI-ACS includes antithrombotic therapy (which may exacerbate bleeding), it is important to identify the cause of anaemia and, in particular, occult bleeds in patients presenting with NSTEMI-ACS. The indication for ICA, access site choice (radial approach favoured), and the need for revascularization should be carefully considered to avoid further blood loss.<sup>453,454</sup> Equally, the choice of antithrombotic agent requires evaluation of ischaemic and bleeding risks, favouring the use of shorter half-life or reversible agents. In the setting of anaemia related to an unknown/untreatable source, the use of DES should be limited to the new-generation devices with proven safety profiles on short-term DAPT.<sup>455</sup> Blood transfusion is discussed in [section 5.4.9](#).

J Am Heart Assoc. 2019

More often **ACS patients with anemia:**

- are **older, women, lower BMI**
- **comorbidities:** previous CV disease, CKD, hyperlipidemia, hypertension, DM, smoking, CAD, previous stroke, HF, malignancy, history of major bleeding
- More frequent **presentation with STEMI/Killip 3-4**
- No difference in time from symptoms onset to PCI
- **Higher median peak value of high sensitivity cardiac troponin T**
- **Lower LV EF**

## events

**Patients with severe anemia (Hb <10 g/dL) had a**

- **10 times higher mortality rate,**
- **6 times higher rate of myocardial reinfarction,**
- **3 times higher rate of major bleeding at 180 days**

## high risk of bleeding and high risk for ischemic

# ANEMIA E SCA

## WHY A WORSE OUTCOME?

**Anemia is a Marker of a preexisting, systemic underlying disease** state defining a “more fragile” patient.

**Systemic inflammatory response syndrome** reduces the capacity for vascular healing → decreased levels of peripheral circulating endothelial progenitor cells in ACS patients affected by anemia on admission compared to non-anemic subjects.

**The systemic effects of the inflammatory response induced by myocardial necrosis** are not just limited to blunted erythroid function but also involve the ability to produce or mobilize endothelial progenitor cells by the bone marrow. This, in turn, may compromise the vascular healing capacity and contribute to poor prognosis of patients with ACS and anemia.

Anemia may impact on the outcome because anemic patients **may not receive guideline-recommended treatment for ACS.**

# Anemia and ACS: to treat or not to treat?

Transfusion practice and outcomes in non-ST-segment elevation acute coronary syndromes

American Heart Journal

Karen P. Alexander MD<sup>a, B</sup>, Anita Y. Chen MS<sup>a</sup>, Tracy Y. Wang MD<sup>a</sup>, Sunil V. Rao MD<sup>a</sup>, L. Kristin Newby MD, Volume 155, Issue 6, June 2008, Pages 1047-1053

## Conclusion

Anemia and transfusion are common in the care of NSTEMI ACS. The observed association between transfusion and adverse outcomes is neutral in the nadir HCT range where transfusions are most often given and trends strongly to benefit when nadir HCT is  $\leq 24\%$ . Although reassuring, randomized trials are needed to confirm the safety of transfusion in NSTEMI ACS. In the meantime, avoiding the need for transfusion is the best approach.

Blood transfusion and ischaemic outcomes according to anemia and bleeding in patients with non-ST-segment elevation acute coronary syndromes: Insights from the TAO randomized clinical trial

P. Deharo<sup>a,b,c</sup>, G. Ducrocq<sup>d,e</sup>, C. Bode<sup>e</sup>, M. Cohen<sup>f,g</sup>, T. Cuisset<sup>a</sup>, S.R. Mehta<sup>g</sup>, C.V. Pollack<sup>h</sup>

*International Journal of Cardiology* 318 (2020) 7–13

In patients with NSTEMI, RBC transfusion was associated with an increase of risk of death or MI at 180 days. This worse outcome appeared more pronounced in case of transfusion without overt bleeding and for hemoglobin level  $> 9.0$  g/dL. This suggests that it may be prudent to refrain from RBC transfusion in those patients who do not have overt bleeding and have preserved hemoglobin levels. Randomized trials are required to better define patients who will benefit from RBC transfusion after a NSTEMI.

Circulation . 2022 Feb 8;145(6):486-488.

## ANEMIA Treatment

The **adequate transfusion threshold** is still being debated, although **current guidelines recommend correction of anemia <8 g/dL**, except for *hemodynamically unstable ACS patients who could benefit from Hb levels between 8 and 10 g/dL*. **No evidence supports** the use of iron supplements and erythropoiesis-stimulating agents in the setting of ACS

**Recommendations for bleeding management and blood transfusion in non-ST-segment elevation acute coronary syndromes for anticoagulated patients**

Recommendations	Class <sup>a</sup>	Level <sup>b</sup>
In patients with dabigatran-associated ongoing life-threatening bleeding, the administration of the specific antidote for dabigatran — idarucizumab — should be considered. <sup>264</sup>	IIa	B
In patients with VKA-associated life-threatening bleeding events, rapid reversal of anticoagulation with four-factor prothrombin complex concentrate rather than with fresh frozen plasma or recombinant activated factor VII should be considered. In addition, repetitive 10 mg i.v. doses of vitamin K should be administered by slow injection.	IIa	C
In patients with NOAC-associated ongoing life-threatening bleeding, the administration of prothrombin complex concentrates or activated prothrombin complex concentrates should be considered when the specific antidote is unavailable.	IIa	C
In patients with rivaroxaban-, apixaban-, or edoxaban-associated ongoing life-threatening bleeding, the administration of the specific antidote — andexanet-alpha — may be considered. <sup>265</sup>	IIb	B
In patients with anaemia and no evidence of active bleeding, blood transfusion may be considered in case of compromised haemodynamic status, haematocrit <25%, or haemoglobin level <8 g/dL.	IIb	C

## Coronary Interventions

### Blood Transfusion and the Risk of Acute Kidney Injury Among Patients With Acute Coronary Syndrome Undergoing Percutaneous Coronary Intervention

Wassef Karrowni, MD; Amit Navin Vora, MD; David Dai, PhD; Daniel Wojdyla, MSc;  
Habib Dakik, MD; Sunil V. Rao, MD

**9% of ACS patients undergoing PCI developed AKI**

Blood transfusion was utilized in 2.2% of patients

**AKI developed in 35.1% of patients who received transfusion versus 8.4% of patients without transfusion** (adjusted odds ratio, 4.87 [4.71–5.04])

**Risk factors** to develop AKI: age, women, comorbidities (diabetes mellitus, hypertension, CKD).

→ **independent association between blood transfusion and AKI in ACS patients undergoing PCI.** This association was significant even among patients with anemia at baseline and who did subsequently sustain a bleeding event, **suggesting that a restrictive blood transfusion policy needs to be further investigated for its potential to improve the safety of PCI.**

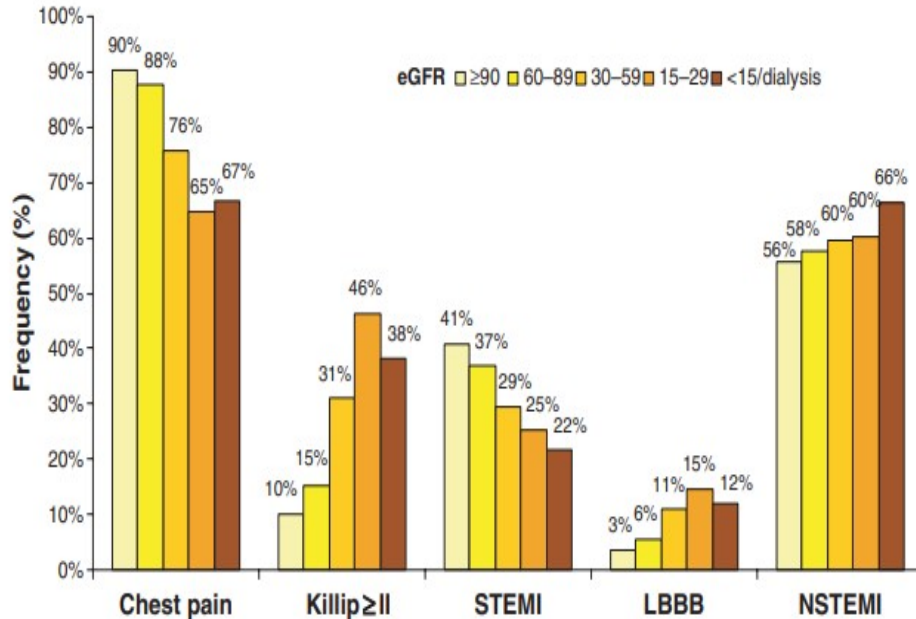

## CKD

- 13% general population → 20-25% ACS patients
- CKD affect every stage of diagnostic and therapeutic pathway of ACS, with an important prognostic relevance
- In all patients with NSTEMI-ACS, **assessment of kidney function by eGFR is recommended for prognostic reasons and to identify patients at risk of contrast-induced nephropathy (Liv I C)**
- Hs-cTn assays maintain high diagnostic and prognostic accuracy and, therefore, clinical utility in patients with renal dysfunction.

A threshold of <5 ng/L may rule out myocardial injury in this population

## Renal function and in-hospital events in ACS

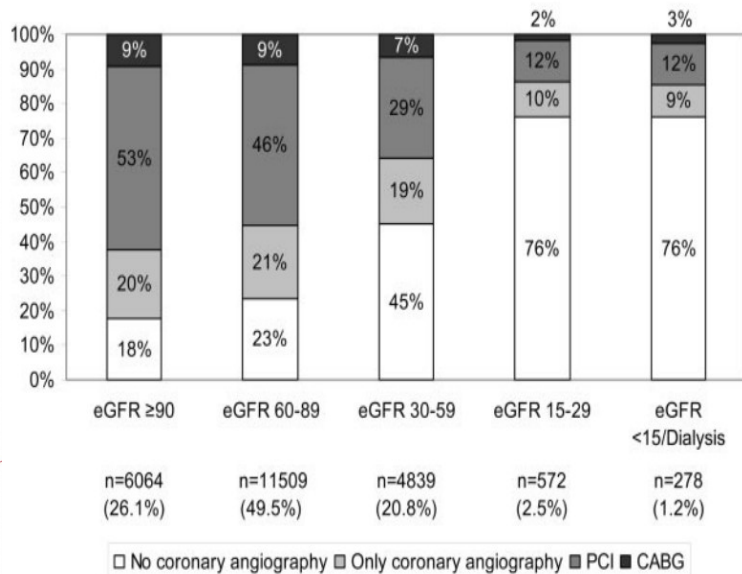

## Kidney Disease and Clinical Presentation of CHD

Characteristic	Acute Myocardial Infarction (n = 803)	Stable Exertional Angina (n = 419)	p Value

## CORONARY HEART DISEASE

## Influence of Renal Function on the Effects of Early Revascularization in Non-ST-Elevation Myocardial Infarction

Data From the Swedish Web-System for Enhancement and Development of Evidence-Based Care in Heart Disease Evaluated According to Recommended Therapies (SWEDEHEART)

23 262 consecutive non-ST-elevation myocardial infarction patients < 80 years old were included in a nationwide coronary care unit register between 2003 and 2006.

## Estimated hazard ratio for mortality at 1 year

# REVASCULARIZATION and CKD

Myocardial revascularization in patients with CKD		
Use of low- or iso-osmolar contrast media (at lowest possible volume) are recommended in invasive strategies. <sup>205,441,442,445,446</sup>	<b>I</b>	<b>A</b>
Pre- and post-hydration with isotonic saline should be considered if the expected contrast volume is >100 mL in invasive strategies.	<b>IIa</b>	<b>C</b>
As an alternative to the pre- and post-hydration regimen, tailored hydration regimens may be considered. <sup>441,448</sup>	<b>IIb</b>	<b>B</b>
CABG should be considered over PCI in patients with multivessel CAD whose surgical risk profile is acceptable and life expectancy is >1 year. <sup>449,450</sup>	<b>IIa</b>	<b>B</b>

© ESC 2020

CABG = coronary artery bypass graft(ing); CAD = coronary artery disease; CKD = chronic kidney disease; eGFR = estimated glomerular filtration rate; PCI = percutaneous coronary intervention.

<sup>a</sup>Class of recommendation.

<sup>b</sup>Level of evidence.

# MEDICAL THERAPY:

## 2020 ESC Guidelines for the management of acute coronary syndromes in patients presenting without persistent ST-segment elevation

The choice and dose of antithrombotic drugs should be carefully considered in patients with CKD, as these patients have an increased risk of bleeding

for patients with stage 5 CKD (eGFR <15 mL/min/1.73 m<sup>2</sup>), there are insufficient safety and efficacy data for the use of P2Y<sub>12</sub> receptor inhibitors

ESC Guidelines

## 12 Key messages

- **Pre-treatment with P2Y<sub>12</sub> receptor inhibitors.** Routine pre-treatment with a P2Y<sub>12</sub> receptor inhibitor in NSTEMI-ACS patients in whom coronary anatomy is not known and an early invasive management is planned is not recommended given the lack of established benefit. However, it may be considered in selected cases and according to the bleeding risk of the patient.

Class 4 (CMI ≥ 5)	431 (9.8)

AECOPDs accounts for 0.5% of ED visits and are economically onerous. Patients with AECOPD attending the EDs are old, frequently affected by several comorbidities, and are burdened by a high prevalence of an adverse outcome.

# COPD and acute myocardial infarction

Cite this article as: Goedemans L, Bax JJ, Delgado V. COPD and acute myocardial infarction. *Eur Respir Rev* 2020; 29: 190139 [<https://doi.org/10.1183/16000617.0139-2019>].

In a UK registry of more than 1 million patients (among those 29870 patients had COPD) attending primary care facilities, the prevalence of AMI was 3.5-times higher in COPD patients compared to patients without COPD (hazard ratio (95% CI) 3.53 (3.02–4.13)) [28]. A similar study performed by SCHNEIDER *et al.* [29] followed 35772 COPD patients from the moment of COPD diagnosis and an equal number of non-COPD patients for incident cardiovascular disease during follow-up. The relative risk estimate for incident AMI was 1.40-fold higher among COPD patients compared to non-COPD patients [29]. This relative risk increased up to 3.00 (95% CI 1.53–5.86) for patients with severe COPD [29].

## 2020 ESC Guidelines for the management of acute coronary syndromes in patients presenting without persistent ST-segment elevation: *supplementary data*

In general, oxygen administration is indicated in hypoxic patients with oxygen saturation <90% or in patients with respiratory distress. Interestingly, prior studies have suggested that hyperoxia may be harmful in some patients, presumably due to increased myocardial injury.<sup>41</sup> Therefore, routine oxygen administration is not recommended in cases of oxygen saturation >90%.

## British Thoracic Society Guideline for oxygen use in adults in healthcare and emergency settings

B R O'Driscoll, L S Howard, J Earis and V Mak on behalf of the BTS Emergency Oxygen Guideline Development Group

**If patients have COPD or other risk factors for hypercapnic respiratory failure, aim at a saturation of 88–92% pending blood gas results but adjust to 94–98% if the PCO<sub>2</sub> is normal (unless there is a history of respiratory failure requiring NIV or IMV) and re-check blood gases after 30–60 min, see table 4.**

F13. In myocardial infarction and acute coronary syndromes, aim at an oxygen saturation of 94–98% or 88–92% if the patient is at risk of hypercapnic respiratory failure (grade D).

# Beta-blockers in COPD: time for reappraisal

Editorial comment in *Eur Respir J* 2016; 48: 600–603.

Brian Lipworth<sup>1</sup>, Jadwiga Wedzicha<sup>2</sup>, Graham Devereux<sup>3</sup>, Jørgen Vestbo<sup>4</sup> and Mark T. Dransfield<sup>5,6</sup>

The main indications for beta-blockers in patients with COPD are post-myocardial infarction and heart failure with reduced ejection fraction. Despite clear evidence beta-blockers improve outcomes in these COPD patients they remain significantly underused due to concerns about adverse respiratory effects, even with beta-1 selective antagonists.

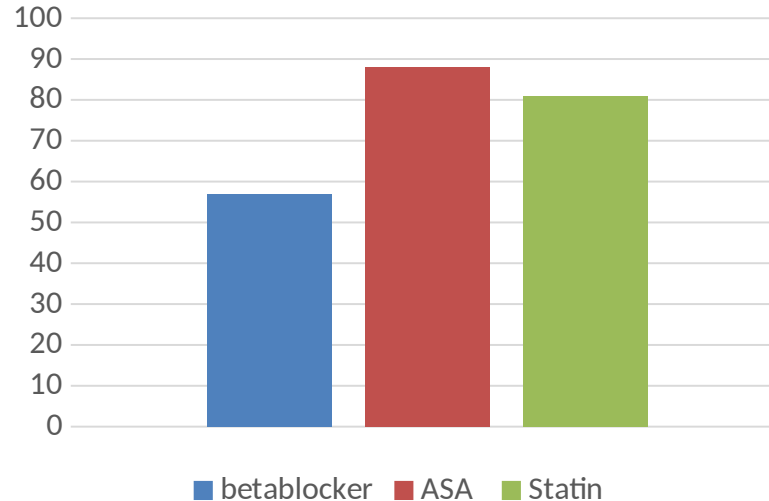

Meta-analyses of retrospective studies with beta-blockers in COPD have shown pooled estimates for reductions in mortality of 28% and exacerbations of 38%.

## Underuse of beta-blockers by patients with COPD and co-morbid acute coronary syndrome: A nationwide follow-up study in New Zealand

- 83 435 patients aged  $\geq 45$  years, with 290 400 person-years of follow-up.

2637 patients with  
 $\geq 1$  ACS admission

Patients with higher COPD severity were less likely to receive a beta-blocker than those with lower severity, as were those with no history of previous ACS and/or heart failure

## Acute HT mediated organ damage

Aorta – dissection, aneurysm

Heart – MACE, acute pulmonary oedema

Brain – stroke, HT encephalopathy

Retina & Kidneys – malignant hypertension

## 5.1 Pharmacological treatment of ischaemia

### 5.1.1 General supportive measures

The goal of pharmacological anti-ischaemic therapy is **to decrease myocardial oxygen demand (secondary to a decrease in heart rate, blood pressure, preload or myocardial contractility)** or to increase myocardial oxygen supply (by administration of oxygen or through coronary vasodilation) *European Heart Journal 2016*

Recommendations	Class <sup>a</sup>	Level <sup>b</sup>
Early initiation of <u>beta-blocker</u> treatment is recommended in patients with ongoing ischaemic symptoms and without contraindications.	I	B
It is recommended <u>to continue</u> chronic beta-blocker therapy, unless the patient is in Killip class III or higher.	I	B
Sublingual or i.v. nitrates are recommended to relieve angina; <sup>d</sup> i.v. treatment is recommended in patients with recurrent angina, uncontrolled hypertension or signs of heart failure.	I	C

Indication	Drugs	Goal of treatment	BP goal
<b>Acute coronary syndrome + HT Emergency</b>	Nitroglycerin, (sodium nitroprusside), labetalol, metoprolol, esmolol, nicardipine	Reduce cardiac workload and improve coronary perfusion	Reduce ~ 25 % of baseline BP in 3-4 hours

# Cardiac Rupture in a Young Male Cocaine User

Adelaide Conti, Anna Paini, Chiara Rossetti, Marzia Bernini, Maria Lorenza Muiesan, Massimo Salvetti

A 25-year-old man was found unconscious by his wife in the bathroom of his apartment. She called emergency services and cardiopulmonary resuscitation was promptly initiated within a few minutes. The patient was intubated, transferred to the Emergency Department (ED) of a local hospital, and after 1 hour of advanced cardiac life support he was pronounced dead. His relatives reported a history of cocaine abuse; he had complained of epigastric discomfort during the previous 2 days

# Cocaine and the Heart

Robert A. Kloner, M.D., Ph.D., and Shereif H. Rezkalla, M.D.

## Treatment

- nitroglycerin, oxygen, aspirin, benzodiazepines, or calcium antagonists, alpha blockers
- **Beta-blockers should be administered with caution, since their use may worsen vasospasm** by allowing unopposed stimulation of alpha receptors.

# Conclusioni

- I pazienti con SCA sono frequentemente affetti da altre malattie che condizionano l'approccio diagnostico e terapeutico
- La presenza di comorbidità dovrebbe essere sempre considerata per ottimizzare il trattamento, allo scopo di migliorare la sopravvivenza del paziente, sia per quanto riguarda la/e malattia/e preesistenti che l'evento coronarico acuto

# SCOMPENSO CARDIACO nella SCA

Terapia in acuto: ossigeno

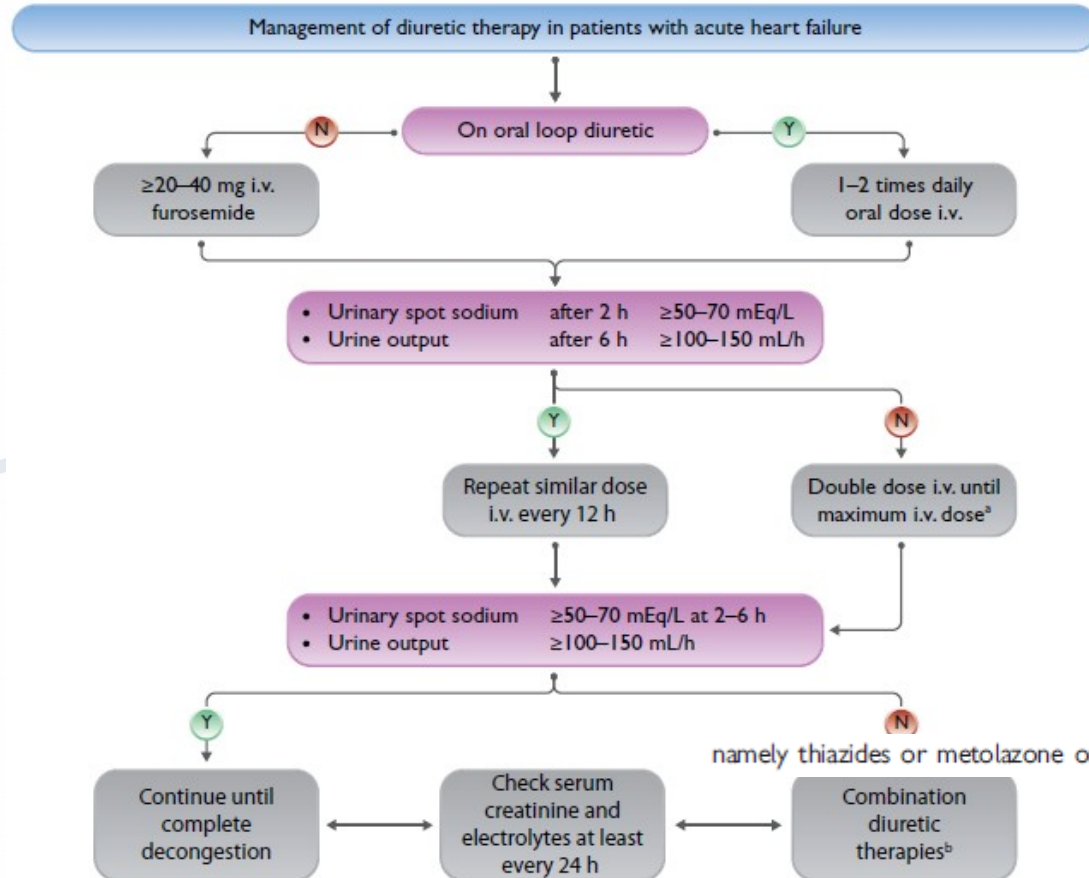

## 2021 ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure

Oxygen is recommended in patients with $\text{SpO}_2 < 90\%$ or $\text{PaO}_2 < 60 \text{ mmHg}$ to correct hypoxaemia.	<b>I</b>	<b>C</b>
Non-invasive positive pressure ventilation should be considered in patients with respiratory distress (respiratory rate $> 25 \text{ breaths/min}$ , $\text{SpO}_2 < 90\%$ ) and started as soon as possible in order to decrease respiratory distress and reduce the rate of mechanical endotracheal intubation. <sup>448</sup>	<b>IIa</b>	<b>B</b>

In AHF, oxygen should not be used routinely in non-hypoxaemic patients, as it causes vasoconstriction and a reduction in cardiac output.<sup>457</sup>

# SCOMPENSO CARDIACO nella SCA

Terapia in acuto: diuretici sì, ma quanto?

# SCOMPENSO CARDIACO nella SCA

Terapia in acuto: vasodilatatori

Intravenous vasodilators may be considered to relieve AHF symptoms when SBP is  $>110$  mmHg. They may be started at low doses and uptitrated to achieve clinical improvement and BP control. Nitrates are generally administered with an initial bolus followed by continuous infusion. However, they may also be given as repeated boluses. Nitroglycerine can be given as 1–2 mg boluses in severely hypertensive patients with acute pulmonary oedema.

Controindicata se :

- Ipotensione
- Sospetto infarto ventricolo destro
- Bradicardia o tachicardia marcate
- Utilizzo inibitori fosfodiesterasi nelle 24 ore precedenti
- Cardiomiopatia ipertrofica
- Stenosi aortica grave

# SCOMPENSO CARDIACO nella SCA

Terapia in acuto: oppioidi

**2017 ESC Guidelines for the management of acute myocardial infarction in patients presenting with ST-segment elevation**

Severely symptomatic patients with pulmonary congestion may also need i.v. morphine to reduce dyspnoea and anxiety, but routine use is not recommended due to concerns about its safety, as it may induce nausea and hypopnea.

# SCOMPENSO CARDIACO nella SCA

Terapia in acuto: inotropi

2017 ESC Guidelines for the management of acute myocardial infarction in patients presenting with ST-segment elevation

Dobutamine is the initial therapy for patients with predominant low cardiac output, whereas norepinephrine may be safer and more effective than dopamine in patients with cardiogenic shock and severe hypotension.<sup>428</sup>

The ESC Textbook of Intensive and Acute Cardiovascular Care (2 ed.)

**ACCA**  
Acute Cardiovascular  
Care Association  
European Society of Cardiology

Norepinephrine should be titrated, until the systolic arterial pressure rises to at least 80 mmHg. Subsequently, IV dobutamine, due to its  $\beta_2$ -adrenergic effects, may be given simultaneously, in an attempt to improve cardiac contractility [48].

## 2021 ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure

### Inotropic agents

Inotropic agents may be considered in patients with SBP <90 mmHg and evidence of hypoperfusion who do not respond to standard treatment, including fluid challenge, to improve peripheral perfusion and maintain end-organ function.<sup>387</sup>

IIb

C

### Vasopressors

A vasopressor, preferably norepinephrine, may be considered in patients with cardiogenic shock to increase blood pressure and vital organ perfusion.<sup>485–487</sup>

IIb

B

# Acute heart failure

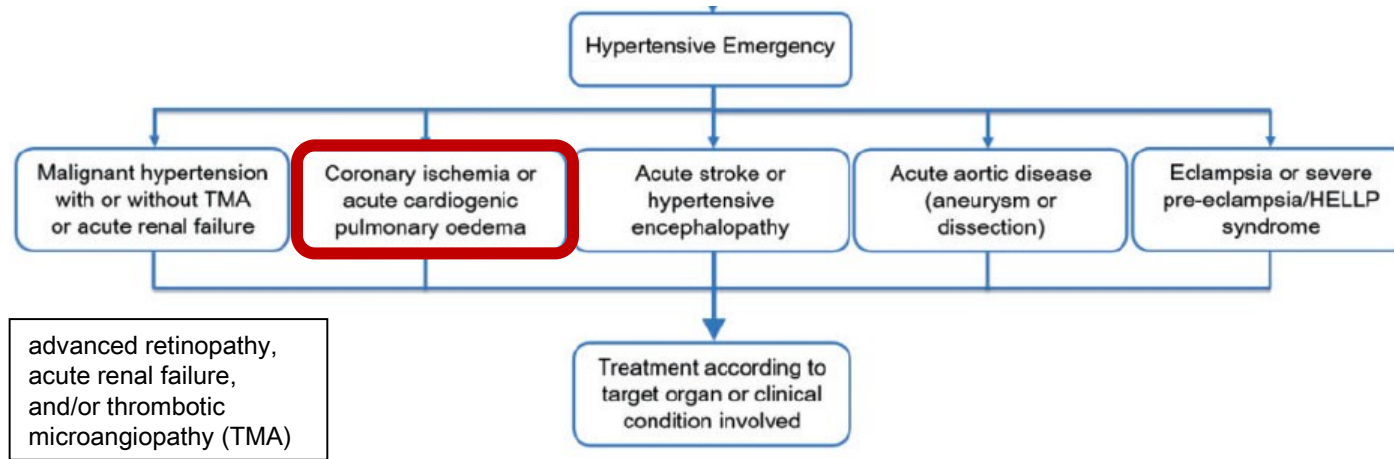

- The diagnosis of NSTEMI-ACS in the context of acute heart failure can be challenging because patients with acute heart failure
  - may present with chest discomfort
  - myocardial injury with troponin elevation can occur in the absence of obstructive CAD
  - the ECG may not be interpretable (bundle branch block or paced rhythm).
- Consequently, coronary angiography may be required to establish a diagnosis of NSTEMI-ACS

# Acute HF during ACS

- The management of acute heart failure should follow current guideline recommendations.
- Emergency echocardiography should be performed to gather information about the LVEF, regional wall motion abnormalities, right ventricular function, presence of valvular heart disease, and volume loading.
- The revascularization strategy should be based on the coronary anatomy, LV function, comorbidities, functional relevance of stenoses, and estimated surgical risk according to a Heart Team consensus, and based upon current recommendations.

## Stratification of hypertensive emergencies according to the condition or target organ involved

Acute and severe increases in BP can be precipitated by pheochromocytoma or by ingestion of sympathomimetics (meta-amphetamine or cocaine.)  
This can result in a hypertension emergency when there is evidence of acute HMOD

## British Thoracic Society Guideline for oxygen use in adults in healthcare and emergency settings

B R O'Driscoll, L S Howard, J Earis and V Mak on behalf of the BTS Emergency Oxygen Guideline Development Group

**If patients have COPD or other risk factors for hypercapnic respiratory failure, aim at a saturation of 88–92% pending blood gas results but adjust to 94–98% if the  $PCO_2$  is normal (unless there is a history of respiratory failure requiring NIV or IMV) and re-check blood gases after 30–60 min, see table 4.**

F13. In myocardial infarction and acute coronary syndromes, aim at an oxygen saturation of 94–98% or 88–92% if the patient is at risk of hypercapnic respiratory failure (grade D).

Drug	Onset of action	Duration of action	Dose	Contraindications	Adverse effects
Esmolol	1–2 min	10–30 min	0.5–1 mg/kg as bolus; 50–300 mg/kg/min as continuous infusion	History of 2nd or 3rd degree AV block (and in the absence of rhythm support), systolic heart failure, asthma, and bradycardia	Bradycardia
Metoprolol	1–2 min	5–8 h	15 mg intravenous (iv), usually given as 5 mg iv, and repeated at 5 min intervals as needed	History of 2nd or 3rd degree AV block, systolic heart failure, asthma, and bradycardia	Bradycardia
Labetalol	5–10 min	3–6 h	0.25–0.5 mg/kg; 2–4 mg/min until goal BP is reached, thereafter 5–20 mg/h	History of 2nd or 3rd degree AV block, systolic heart failure, asthma, and bradycardia	Bronchoconstriction and foetal bradycardia

## DM 2

### 2020 ESC Guidelines N-STEMI

Patients with diabetes more frequently present with non-typical symptoms than patients without diabetes.

They more frequently have multifocal CAD, less frequently receive guideline-indicated care, and have worse clinical outcomes.

The selection of antithrombotics and an invasive strategy should not differ from those without diabetes.

Compared with clopidogrel, more potent platelet inhibitors have higher absolute risk reductions in patients with diabetes.

## DM 2

### 2020 ESC Guidelines N-STEMI

In critically ill patients, there is a risk of hypoglycaemia-related events when using intensive insulin therapy.

It is not unreasonable to manage hyperglycaemia in patients with NSTEMI-ACS by keeping their blood glucose concentration <200 mg/dL.

#### Recommendations for diabetes mellitus in non-ST-segment elevation acute coronary syndrome patients

Recommendations	Class <sup>a</sup>	Level <sup>b</sup>
It is recommended to screen all patients with NSTEMI-ACS for diabetes and to monitor blood glucose levels frequently in patients with known diabetes or admission hyperglycaemia.	I	C
Avoidance of hypoglycaemia is recommended. <sup>424–427</sup>	I	B
Glucose-lowering therapy should be considered in ACS patients with blood glucose >10 mmol/L (>180 mg/dL), with the target adapted to comorbidities, while episodes of hypoglycaemia should be avoided. <sup>422,428–430</sup>	IIa	B
A multifactorial approach to diabetes mellitus management, with treatment targets, should be considered in patients with diabetes and CVD. <sup>431–436</sup>	IIa	B
Less stringent glucose control should be considered, both in the acute phase and at follow-up, in patients with more advanced CVD, older age, longer diabetes duration, and more comorbidities.	IIa	C

ACS = acute coronary syndromes; CVD = cardiovascular disease; NSTEMI-ACS = non-ST-segment elevation acute coronary syndrome.

<sup>a</sup>Class of recommendation.

<sup>b</sup>Level of evidence.

# DM 2

## 2019 ESC Guidelines on Diabetes, Pre-Diabetes and Cardiovascular Diseases

There is evidence that improved glycaemic control defers the onset, reduces the progression, and (in some circumstances) may partially reverse markers of microvascular complications in patients with DM.

Achieving this without detriment and with benefit to the CV system is an important challenge, particularly when selecting glucoselowering therapies to suit the individual.

### Recommendations for glucose-lowering treatment for patients with diabetes

Recommendations	Class <sup>a</sup>	Level <sup>b</sup>
<b>SGLT2 inhibitors</b>		
Empagliflozin, canagliflozin, or dapagliflozin are recommended in patients with T2DM and CVD, or at very high/high CV risk, <sup>c</sup> to reduce CV events. <sup>306,308,309,311</sup>	I	A
Empagliflozin is recommended in patients with T2DM and CVD to reduce the risk of death. <sup>306</sup>	I	B
<b>GLP1-RAs</b>		
Liraglutide, semaglutide, or dulaglutide are recommended in patients with T2DM and CVD, or at very high/high CV risk, <sup>c</sup> to reduce CV events. <sup>176,299–300,302–303</sup>	I	A
Liraglutide is recommended in patients with T2DM and CVD, or at very high/high CV risk, <sup>c</sup> to reduce the risk of death. <sup>176</sup>	I	B
<b>Biguanides</b>		
Metformin should be considered in overweight patients with T2DM without CVD and at moderate CV risk. <sup>146,149</sup>	IIa	C
<b>Insulin</b>		
Insulin-based glycaemic control should be considered in patients with ACS with significant hyperglycaemia (>10 mmol/L or >180 mg/dL), with the target adapted according to comorbidities. <sup>260–262</sup>	IIa	C
<b>Thiazolidinediones</b>		
Thiazolidinediones are not recommended in patients with HF.	III	A
<b>DPP4 inhibitors</b>		
Saxagliptin is not recommended in patients with T2DM and a high risk of HF. <sup>291</sup>	III	B

ACS = acute coronary syndromes; CV = cardiovascular; CVD = cardiovascular disease; DM = diabetes mellitus; DPP4 = dipeptidyl peptidase-4; GLP1-RA = glucagon-like peptide-1 receptor agonist; HF = heart failure; SGLT2 = sodium-glucose co-transporter 2; T2DM = type 2 diabetes mellitus.

<sup>a</sup>Class of recommendation.

<sup>b</sup>Level of evidence.

<sup>c</sup>See Table 7.

## DM 2 - CKD

### PLATO TRIAL (Platelet Inhibition And Patient Outcomes trial)

Patients with diabetes mellitus (DM) are at increased risk of atherothrombotic events. DM is a key risk factor for the development of chronic kidney disease (CKD), a well-known cardiovascular risk factor.

The PLATO trial was conducted from October 2006 to February 2009 and randomly assigned 18 624 patients with ST-segment-elevation myocardial infarction (MI), non-ST-segment elevation MI, or unstable angina, treated with an invasive or a noninvasive approach, to receive either ticagrelor or clopidogrel as soon as possible after admission

A post hoc analysis of the PLATO (Platelet Inhibition and Patient Outcomes) trial, was conducted to assess clinical outcomes in ACS patients according to the presence or absence of DM and CKD, as well as the differential effects of P2Y<sub>12</sub>-inhibiting therapies (ticagrelor versus clopidogrel) in these populations.

# DM 2 - CKD

## PLATO TRIAL (Platlet Inhibition And Patient Outcomes trial)

Patients randomized in PLATO with available DM and CKD status at the time of randomization were included in the present analysis. Accordingly, patients were classified into 4 groups:

DM+/CKD+      DM+/CKD-      DM-/CKD+      DM-/CKD-

The primary efficacy end point was a composite of cardiovascular death, myocardial infarction, or stroke at 12 months.

The primary safety end point was PLATO major bleeding

Table 1. Baseline Characteristics by DM/CKD Status

Group of Characteristics	Characteristic (n/N)	DM-/CKD- (n=108)	DM-/CKD+ (n=108)	DM+/CKD- (n=108)	DM+/CKD+ (n=108)	P-value

ACE, angiotensinogen converting enzyme; ACS, acute coronary syndrome; AF, atrial fibrillation; BMI, body mass index; CABG, coronary artery bypass graft; CHD, chronic coronary disease; CCI, creatinine clearance by Cockcroft-Gault equation; DM, diabetes mellitus; GP, glycoprotein IIb/IIIa; HbA1c, hemoglobin A1c; MI, myocardial infarction; NTG+P2Y<sub>12</sub> treatment group with a statistically significant P2Y<sub>12</sub> group for each comparison; n, number of patients; TIA, transient ischaemic attack.

## DM 2 - CKD

### PLATO TRIAL outcomes

Compared with clopidogrel, ticagrelor significantly reduced the incidence of the primary end point consistently across subgroups (P interaction=0.3).

However, the absolute risk reduction (ARR) with ticagrelor versus clopidogrel was considerably higher in DM+/CKD+ patients (11.26%; adjusted HR 0.78; 95% CI 0.61–1.01) compared with DM/CKD (1.37%; adjusted HR 0.86; 95% CI 0.73–1.00)

**Figure 5.** Hazard ratios (HR) with 95% CI for the primary composite end point (cardiovascular death, myocardial infarction, and stroke) of ticagrelor (T) vs clopidogrel (C) stratified by DM/CKD status. The model is adjusted for age, sex, body mass index, heart rate, prior myocardial infarction, hypertension, dyslipidemia, angina pectoris, smoking status, previous percutaneous coronary intervention or coronary artery bypass graft, type of acute coronary syndrome, and randomized treatment. CKD indicates chronic kidney disease; DM, diabetes mellitus.

## DM 2 - CKD

### PLATO TRIAL results

There was no increased risk of bleeding with ticagrelor in patients with CKD and DM as compared with the other subgroup

**Table 2.** Ischemic and Bleeding Outcomes According to DM/CKD Subgroup, With Poor Glycemic Control Defined by HbA1c and CKD Defined by the Creatinine-Cystatin C CKD-EPI Equation

DM-/CKD+	86	734	11.7	1.14 (0.90-1.45)	
DM+/CKD+	148	1264	11.7	1.14 (0.94-1.38)	
<b>Non-CABG-related major bleeding</b>					
DM-/CKD--	161	5673	2.8		0.0070
DM+/CKD--	180	5726	3.1	1.00 (0.81-1.25)	
DM-/CKD+	44	734	6.0	1.34 (0.94-1.91)	
DM+/CKD+	88	1264	7.0	1.55 (1.16-2.07)	
<b>CABG-related major bleeding</b>					
DM-/CKD--	367	5628	6.5		0.1678
DM+/CKD--	366	5673	6.5	1.02 (0.88-1.18)	
DM-/CKD+	44	727	6.1	0.96 (0.69-1.32)	
DM+/CKD+	96	1250	7.7	1.29 (1.01-1.65)	

The model is adjusted for age, sex, BMI, heart rate, prior myocardial infarction, hypertension, dyslipidemia, angina pectoris, smoking status, previous PCI or CABG, type of ACS define and randomized treatment. MI/Stroke indicates body mass index; CABG, coronary artery bypass graft; CKD, chronic kidney disease; CKD-EPI, chronic kidney disease epidemiology collaboration; DM, diabetes mellitus; HbA1c, hemoglobin A1c; HR, hazard ratio; MI, myocardial infarction; PCI, percutaneous coronary intervention.

<sup>a</sup>The crude event rate, i.e., events/no. of subjects × 100%.

<sup>b</sup>Subgroup DM-/CKD-- is the reference category.

<sup>c</sup>P value for the effect of DM/CKD subgroup.

## DM 2 - CKD

### PLATO TRIAL conclusion

Subgroup analysis of major clinical trials have shown a reduced benefit of clopidogrel in CKD patients.

Patients with CKD are characterized by upregulation of the P2Y<sub>12</sub> signaling pathway induced by dinucleoside polyphosphates and impaired hepatic function, which can potentially impact clopidogrel metabolism.

Ticagrelor is characterized by more potent and predictable antiplatelet effects compared with clopidogrel, which translate into better clinical outcomes in ACS patients

# DM 2 - CKD

## PLATO TRIAL clinical prespective

DM is a key risk factor for the development of CKD.

One third of DM patients are found to have CKD. Therefore, with the increasing prevalence of DM, which is expected to double over the next 20 years, the prevalence of CKD is also expected to rise.

These observations underscore the need for defining the most effective treatment options for these high-risk patients, including strategies to reduce the risk of developing CKD in patients with DM.

Sodium-glucose cotransporter-2 inhibitors are new antihyperglycemic therapies known to reduce long-term decline in kidney function.

### Clinical Perspective

#### What Is New?

- Acute coronary syndrome patients with diabetes mellitus and chronic kidney disease are at markedly increased risk for long-term atherothrombotic events compared with patients without these risk factors, as well as with those with only 1 of these.
- Although the ischemic benefit of ticagrelor versus clopidogrel was consistent in all patient subgroups, the magnitude of benefit was enhanced according to the patient risk profile.

#### What Are the Clinical Implications?

- There is a need to define the most effective treatment options for these high-risk patients, including strategies to reduce the risk of developing chronic kidney disease in patients with diabetes mellitus.
- Similarly, in patients with established chronic kidney disease, glucose control is also critical to reduce the risk of developing diabetes mellitus.
- Clinicians should use more potent platelet-inhibiting therapy in acute coronary syndrome patients with diabetes mellitus and chronic kidney disease who are often undertreated because of high perceived risk of bleeding.

# PIASTRINOPENIA

## ESC GUIDELINES NSTEMI 2020

Prevalence of **thrombocytopenia in ACS patients: 5-13%**

The presence of thrombocytopenia in ACS patients predicts significantly worse outcomes

### 8.5 Thrombocytopenia

Thrombocytopenia in the context of NSTEMI-ACS is an independent predictor of poor outcomes, including death, major bleeds, and life-threatening prothrombotic events.<sup>167–170</sup> Clinically significant thrombocytopenia is defined as a platelet count  $\leq 100\,000/\text{mL}$  or a relative drop of 50% from baseline. Causes include haemodilution, in vitro artefacts, increased platelet consumption/sequestration/destruction, and decreased platelet production.<sup>170</sup> Blood sampling should be in non-ethylenediaminetetraacetic acid tubes, as ethylenediaminetetraacetic acid may lead to platelet clumping and pseudo-thrombocytopenia.<sup>170</sup>

- Increased risk of adverse outcomes, **regardless of the etiology of the low platelet count**, particularly death and bleeding, in this population of cardiac patients.
- **Bleeding strong independent predictor of an adverse event**
- Thrombocytopenia may be a marker for acuity of illness and often may be only an association between a low platelet count and therapeutic interventions in this population. **Treatment strategies**, both medical and mechanical, may cause thrombocytopenia.

**Evaluation of thrombocytopenia in the acute coronary syndrome**

### CURRENT OPINION

*Acute coronary syndromes*

## The management of antiplatelet therapy in acute coronary syndrome patients with thrombocytopenia: a clinical conundrum

**Table 2** Strategies to minimize bleeding risk in patients with significant thrombocytopenia

- Avoid non-steroidal anti-inflammatory drugs
- Avoid glycoprotein IIb/IIIa inhibitors
- Utilize a proton pump inhibitor unless contraindicated
- Aspirin should be used in low-dose form
- If a patient is already receiving a long-term anticoagulation agent, triple therapy should be avoided
- If a patient is undergoing percutaneous coronary intervention:
  - Radial approach preferred to femoral approach
  - Restrict dual antiplatelet therapy to 1 month post-stent
  - Second generation drug-eluting stent preferred to bare-metal stent

Rapid Risk Stratification of Unstable Angina Patients Suppress Adverse Outcomes With Early Implementation of the American College of Cardiology/American Heart Association Guidelines (CRUSADE) quality improvement initiative. Risks of inpatient mortality and bleeding correlated directly with severity of thrombocytopenia and even mild thrombocytopenia (platelet nadir 100 to  $149 \times 10^9/L$ ) was associated with increased risks of mortality [adjusted odds ratio (OR), 2.01; 95% CI: 1.69 to 2.38] and bleeding (adjusted OR, 3.76; 95% CI: 3.43 to 4.12). Every 10% decrease in platelet count was associated with increased mortality (adjusted ORs: 1.39, 95% CI: 1.33 to 1.46) and bleeding risk (adjusted OR: 1.89, 95% CI: 1.83 to 1.95). Ominously, approximately one in four patients who developed moderate/severe thrombocytopenia did not survive the hospitalization.<sup>6</sup> The influence of the aetiology of thrombocytopenia on prognosis and treatment has not been well investigated and warrants exploration. Liver disease in particular is associated with coagulation disorders as well and therefore may carry even greater bleeding risk in the setting of thrombocytopenia.
